

Phase II Clinical Trial Results: Drug X

A randomized, double-blind Phase II clinical trial was conducted to evaluate the efficacy of Drug X in reducing systolic blood pressure among adults with stage 1 hypertension. Participants were assigned to either a treatment group receiving Drug X or a placebo control group over a 12-week period. The chart below summarizes average systolic blood pressure measurements recorded during the study.

Patients receiving Drug X demonstrated progressive reductions in systolic blood pressure, with statistically significant improvements observed by Week 8. By Week 12, the treatment group showed a 23 mmHg average reduction from baseline, compared to a minimal change in the placebo group.
