

Kubernetes-Based Microservices Architecture Overview

Our platform is built using a microservices-based architecture deployed within a Kubernetes cluster. All external requests pass through a centralized API Gateway behind a load balancer. Core services include an authentication service, user service, and payment service. Persistent data is managed through a distributed PostgreSQL cluster. The diagram below illustrates service interactions and infrastructure components.

Kubernetes-Based Microservices Architecture

Each service runs within isolated Kubernetes pods and communicates via internal service mesh routing. Horizontal scaling is handled automatically based on CPU utilization thresholds.
